## logistic\_regression

## 2022-07-31

2) Complete data model is logistic regression & probability to be missing depends ## only on Y

WTS: If probability to be missing depends ONLY on Y and NOT on X, and missing

data is confined to either Y or X (will confine to just X in our case), then

LD is more efficient (and generates unbiased regression coefficients)

```
create.data \leftarrow function(beta_0 = 0, beta_1 = 1, beta_2 = 2, n = 200){
# Data. Given this.
x1 = rnorm(n)
                        # some continuous variables
x2 = rnorm(n)
# defining z to be this. Coefficents are unknown. They are estimated using MLE as part of
# logistic regression.
z = beta_0 + beta_1*x1 + beta_2*x2
                                           # linear combination with a bias. Here,
\# B_0 = 1, B_1 = 2. The coefficients represent change in log odds. I.e. if
# x2 increases by 2, log odds increase by 2, i.e. odds of a "1" if x2 increases
# by 2 is exp(2) = 7.38 higher than original x2.
pr = 1/(1+exp(-z))
                           # pass through an inv-logit (sigmoid) function to
                           # to constrain to [0,1]; represents odds of event
Y = rbinom(n, 1, pr)
data = as.data.frame(cbind(Y, x1, x2))
}
```

relative to multiple imputation.

## Add Missingness

## **Multiple Imputation**

## [1] 0.2079214

```
